2022-09-23

#The Weigelt Corporation has three branch plants with excess production capacity. Fortunately, the #corporation has a new product ready to begin production, and all three plants have this capability, #so some of the excess capacity can be used in this way. This product can be made in three #sizes—large, medium, and small—that yield a net unit profit of \$420, \$360, and \$300, respectively. #Plants 1, 2, and 3 have the excess capacity to produce 750, 900, and 450 units per day of this #product, respectively, regardless of the size or combination of sizes involved.

#The amount of available in-process storage space also imposes a limitation on the production rates of #the new product. Plants 1, 2, and 3 have 13,000, 12,000, and 5,000 square feet, respectively, of #in-process storage space available for a day's production of this product. Each unit of the large, #medium, and small sizes produced per day requires 20, 15, and 12 square feet, respectively. Sales #forecasts indicate that if available, 900, 1,200, and 750 units of the large, medium, and small #sizes, respectively, would be sold per day.

#At each plant, some employees will need to be laid off unless most of the plant's excess production #capacity can be used to produce the new product. To avoid layoffs if possible, management has decided #that the plants should use the same percentage of their excess capacity to produce the new product. #Management wishes to know how much of each of the sizes should be produced by each of the plants to #maximize profit.

#a. Define the decision variables

#The decision variables are the number of units of the new product, regardless its size, that should be produced on each plant to maximize the company's profit.

#Note:

 $\#X_i$ = means the number of units produced on each plant, where i=1 (Plant 1), 2 (Plant 2), and 3 (Plant 3)

#L, M, and S = means the product's size, where L = large, M = medium, and S = small.

#The decision variables are:

 $\#X_iL$ = number of large items produced on plant i, where i=1 (Plant 1), 2 (Plant 2), and 3 (Plant 3).

 $\#X_iM$ = number of medium items produced on plant i, where i=1 (Plant 1), 2 (Plant 2), and 3 (Plant 3).

 $\#X_iS$ = number of small items produced on plant i, where i=1 (Plant 1), 2 (Plant 2), and 3 (Plant 3).

#b. Formulate a linear programming model for this problem.

#Let

 $\#X_iL$ = number of large items produced on plant i, where i=1 (Plant 1), 2 (Plant 2), and 3 (Plant 3).

 $\#X_iM$ = number of medium items produced on plant i, where i=1 (Plant 1), 2 (Plant 2), and 3 (Plant 3).

 $\#X_iS$ = number of small items produced on on plant i, where i=1 (Plant 1), 2 (Plant 2), and 3 (Plant 3).

#Maximize profit

```
\#Z = 420 (X_1L + X_2L + X_3L) + 360 (X_1M + X_2M + X_3M) + 300 (X_1S + X_2S + X_3S) \#Constraints:
#Total number of size's units produced regardless the plant:
\#L = X_1L + X_2L + X_3L
#M = X_1M + X_2M + X_3M
\#S = X_1S + X_2S + X_3S #Production capacity per unit by plant each day:
#Plant 1 = X_1L + X_1M + X_1S 750
#Plant 2 = X_2L + X_2M + X_2S 900
#Plant 3 = X_3L + X_3M + X_3S 450 #Storage capacity per unit by plant each day: #Plant 1 = 20X_1L +
15X_1M + 12X_1S 13000
#Plant 2 = 20X_2L + 15X_2M + 12X_2S 12000
#Plant 3 = 20X_3L + 15X_3M + 12X_3S 5000
#Sales forecast per day:
\#L = X_1L + X_2L + X_3L 900
#M = X_1M + X_2M + X_3M 1200
\#S = X_1S + X_2S + X_3S 750 \#The plants should use the same percentage of their excess capacity to produce
the new product.
\#\frac{X_1L + X_1M + X_1S}{750} = \frac{X_2L + X_2M + X_2S}{900} = \frac{X_3L + X_3M + X_3S}{450}
#It can be simplified as: #a) 900(X_1L + X_1M + X_1S) - 750(X_2L + X_2M + X_2S) = 0
#b) 450(X_2L + X_2M + X_2S) - 900(X_3L + X_3M + X_3S) = 0
#c) 450(X_1L + X_1M + X_1S) - 750(X_3L + X_3M + X_3S) = 0
#All values must be greater or equal to zero
\#L, M, \text{ and } S > 0
\#X_iL, X_iM, and X_iS > 0
